(54) IMPROVEMENTS IN AND RELATING TO BORE HOLB DRILLING

(71) We, COMPAGNIE FRANCAISE DES PETROLES, a French corporate body, of 5 rue Michel-Ange, Paris 16 cms. France, do hereby declare the invention, for which we pray that a patent for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:

The present investigation

The present invention is concerned with exploratory drilling and in particular to the protection of a drilled hole against caving in and ingress of water.

Known methods, in spite of the progress schieved, all have the common characteristic of protecting the drilled hole against caving in of the strata passed through by means of tubes which are sent down as the drilling descends. This type of protection which is costly, due both to the time required to place the tubes in position and the mandhandling involved and to the cost of the tubes used, is particularly troublescense in the case where drilling methods, known as rotary drilling methods are employed, because of a loss of power, due to Known methods, in spite of the progress known as rotary drilling methods are employed, because of a loss of power, due to rubbing of the drilling tool drive shaft against the walls of the bore hole, is added to the above disadvantage. This loss of power may be considerable because this staft may be as much as several miles in length. Furthermore, when the tools require changing it is necessary to raise the drive shaft, which comprises lengths of rod screwed one into the other, and unscrew it thus increasing the cost price of this type of thus increasing the cost price of this type of protection.

The method of bore-hole drilling called "flexidrilling" achieves a net advance over rotary methods because the drive shalt is replaced by a flexible armoured hose for the hold driving motor and the flexible hose can tool driving motor and the liexible hose can be wound up or unwound by means of a drum. In addition, the space takes up by the drilling platform can be reduced in size. However this method does not dispense with the need to grotect the drilled hole using steel tubes to prevent caving in of the strats. Purthermore, it is essential to ensure a perfect seal round the flexible hose so as to avoid the considerable danger if an cruption

According to one aspect of the present invention there is provided a method of exploratory drilling comprising deiling a hole and moulding a tobing around the wall of the drilled hole simultaneously with drilling of the hole, the tube preventing cardina in of the strate and increase of water. caying in of the strata and ingress of water,

According to another aspect of the present invention there is provided a present invention there is provided a method of exploratory drilling comprising drilling a hole by passing a drilling tool downwardly through the earth, moulding a tubing around the wail of the drilled hole simultaneously with the downward movement of the drilling tool, to prevent caving in of the strats and ingress of water, wherein an expandable member carried by the drilling tool is expanded laterally against the moulded tubing so as to prevent relative movement between the expandable member and the tubing and a force is exerted beand the tabing and a force is exerted be-tween the stationary expandable member and the drilling tool to cause the drilling tool

and the drilling tool to cause the drilling tool to progress downwardly.

Thus, on the surface, instead of having a large stock of pipes always available, which are assembled one to the other as drilling progresses, it is only necessary to have available a stock of moulding materials which are tipped into appropriate tanks, from which they are led into a tubing former connected with and above the drilling tool. By use of this method the strata can be supported immediately after drilling.

The portion of tubing in the process of being moulded may be protected from the drilled strata by a sheave which is moulded below it. This enables the tubing to be effectively protected during its moulding process because it is enough to ensure that the sleeve former and drilling tool holder are offectively sealed for the tubing former are effectively sealed for the tubing former to be protected from the strate and, as a result, all water ingress.

85

suit the drilling depth thus ensuring an injection pressure for the resins at formers 15 and 16 which is 30 bars higher than that at the bottom. Flexible kozes 33 and 34 are heated thus ensuring that the viscosity of the material is not howered. A valve 37 enables the introduction of hardener late a static mixer 38 to be stopped. This allows static mixer 38 to be drained of hardener, in the event of a temperary step in delillar hardener. event of a temporary stop in drilling, before valve 39, which controls the feed of resin to injection zones 19 or 20, according to whether tubing 8 or sleeve 6 is being made, is closed. It will be understood that two assemblies exist similar to that shown in Figure 6, one for the sleeve 6, the other for the tubing 8.

Thus it will be understood that circuits 5 and 7, illustrated in Figure 1, each comprise two channels, one for the resin and the other for the bardener, the channel for the latter for the berusher, the thinking for the same being provided with a valve such as 37 located on the inlet side of a static mixer such as 38. Likewise, valves such as 39 control the flow of each of the resins and they are located one in channel 7 near lajection zone 19 and the other in channel 5 near injection zone 20.

The advancement of drilling and the forming of tubing 8 and its sleeve 5 are carried out as librarated diagrammatically carried out as illustrated diagrammatically in Figures 3 to 5. In Figure 3, aboves 11 and 12 are illustrated deflated and inflated respectively. Sheeve 11 is fast with body 10 and descends with body 10 as a result of oil pressure, in the general circuit 23, awarded on piston 40, itst with body 10, under the control of control unit 9 (Figure 6). Oil entering the top part of cylinder 42 via circuit 41 pushes the piston down, sleeve 12 remaining firmly applied against tubing 8 by previous inflation of the sleeve. Thus, as tool 2 progresses downwards, body 10 descends relative to sleeve 12. Formers 15 and 16 fast with body 10 also descend and, during this with body 10 also descend and, during this movement, a cortain amount of resin is extruded in zone 20 to form alcove 6, the resin gradually polymerising in the regions of the heating element 18, whereas resin extruded in zone 19, the flow of which is different from the resin used in the muking of sleeve 6, polymerises near heating element 17 to form tubing 8. It is of course understood that the quantities injected are in proportion to the downward progress of the tool and the thickness of the respective

the tool and the thickness of the respective sleeve or tubing. For example, the sleeve of may be about 10 mm thick and the tubing 8 about 50 mm thick. The control unit 9 controls the supply of resins.

The tool continues to advance downwards until photon 40 reaches the bottom of cylinder 42, Figure 4. This leads to the immediate inflation of sleeve 11, Figure 5, which holds the body 10 while sleeve 12 is

deflated to enable it to take up a lower position as the result of injection of oil into the part of cylinder 42 located below piston 40. The automatic inflation of sleeve 11 may 40. The sittematic influence of allows 11 may be ensured by an electrical impulse from an end of stroke stop 58, the impulse being transmitted by wire 61 to control unit 9. Figure 8. As solement flap valve control circuits which control hydraulic feed to the hydraulic circuits are well known, details of the maintained describes are stated in the finite and hydraulic circuits are well known, account or the various circuits ensuring inflation and deflation of the sierces have not been illustrated. Thus, during a period of time which may be very short, sierce 12 moves down to a lower level so that when the top of cowinto a lover love to that which they converted to the control of the control o muss concurred mastrated in Figure 3. For this purpose an end of stroke stop 59 may be used which sends a releasing impulse by wire 60 to control unit 9 (Figures 1 and 8). In Figure 8, then, are found the oil circuit 23,

wire 60 to control unit 9 (Figures 1 and 8). In Figure 8, then, are found the oil circuit 23, resin supply circuit 5 and 7 and mud circuit 4 comprising a down channel 4a and an up channel 4b in some Z, Figure 7.

A high pressure pump 45 supplies the oil necessary to inflate formers 15, 16, shirid 22 and slowers 11 and 12. A first circuit 43 leads to controls C15, C16 and C22 for inflating formers 15, 16 and shield 22. In the same way a second circuit 44 leads to controls C11 and C12 for alceves 11 and 12. The assembly of circuits 48, 49 and 50 controlling controls C15, C16, and C22, and circuits 46 and 47 controlling controls C11 and C12 are placed under the control of the general control 51 for advancing or stopping the forming machine and in consequence pirton 40, the movement of which depends on the oil fed via circuit 41. Circuit 41, serving channels C22s and C42b controlled by control channels 62 and 63 from the general control 51, enables, via channel C42s, the drill to advance downwards and the sleeve 6 and tubing 8 forming machine to descend simultaneously, and enables, via channel to descend simultaneously, and enables, via channel to descend simultaneously, and enables, via channel of and simultaneously, and enables, via channel of and simultaneously, and enables, via channel tubing 8 forming machine to descend simultaneously, and enables, via channel C42b, cylinder 42 to descend after defiation of sleeve 12. Wires 61 and 60 transmit the impulses sent out by the end of stroke stops
58 and 59 to the general control 51 in order
to control the automatic setting in motion of the inflating and deflating operations for sloeves 11 and 12 via control channels 46 sleeves 11 and 12 via control channels 40 and 47. The mud circuit 4 is also placed under the control of coatrols CE, CP and CG for three valves B, F, G (Figure 7), these controls being placed under the control of control unit 51 by channels 64, 65 and 66. Valves B and F may be closed in the svent of the forming machine being stopped or due to detection of a high pressure zone by detector 53 coupled to control unit 51 by CS3. In this Illustration, the zone including C53. In this illustration, the zone including 130

the tube making manhine, and the inflatable sleeves, has been indicated by the letter Z. the bottom of the drilling. Thus the retractable tool 2, during its descent, advances its head gradually downwards in the The moulding sone has been indicated by the letter M. As far as the mud circuit is concerned, it is seen that it is fad in by flexible hose 3 and returned by channel 4b in sanuther section A. Supply circuits 5 and 7 for resins and hardesters are placed under the control of controls C35, C36 and C35, C'36 as well as controls C37 and C'37 controlling valves 37 for the hardener circuits and C 39 and C'39 controlling valves 39 for the resins sapply. A channel 54 connects control unit 51 to controls C35 to C'36 thus bringing the resin flow under a control relative to the speed of advance by any desired method, channel C53 also The moulding zone has been indicated by vances its head gradually downwards in the tubing and cuts a wall in a truncated shape until meeting up with the protecting sleeve. This truncated shape cutting may alternatively be carried out by a boring sleeve, this sleeve being located just above the drilling tool. If a cement plug has bean poured, it is broken up by sneams of the drilling tool, the presence at the bottom being contained by the clamps on the machine in the conventional way. When former 15 resolves the point where the truncated portion commences, resin is injected without bardener thus forcing out the much then the controls are set for the feed of hardener and resin. While the machine is descending and as soon as former 16 reaches the bottom end of the truncated coun, the controls are set for any desired method, channel C53 also enabling this flow to be brought under a control relative to the pressure existing at the bottom of the drilling transmitted by pressure seasor 53 by any desired method. Control unit 51 is operated consequently from the surface by line T.

In addition to these controls, a dotted line C. 53 has been illustrated to show a special connection the object of which is to sand a truncated come, the controls are set for runcated come, the controls are set for forming the outer alcove. In this manner a perfect joint is made between the earlier tubing and a new section of tubing, the end of the new alcove being held between two truncated leyers of tubing resin. Thus the machine constructed enables a perfect tubing joint to be made after an interception. C'53 has been illustrated to show a special connection the object of which is to send a signal set in motion by very high pressure or an cruption. This signal, by means of connection 55, enables the flow of retins to be stopped and heating of heating elements 17 and 18 of formers 15 and 16 to be switched off, by means of connection 56 for controlling the closure of the mud circuit valves E and F and by means of connection 57 for controlling the inflation of sleeves 11 and 12, with the object of locking the machine and proceeding to insert a coment plug. It is saif-evident that the thermohardening materials which may be used to form the sloeve and tubing can be of any sort provided that their mechanical properties are sufficient to take the place of conventional tubing. Thus the invention enventional tubing. companies the case of forming a tubing 8 without making a sleeve 5.

In addition to the above-mantioned plug.

As these various circuits can be of any In addition to the above-mantioned applications, that is to say bore-hole drilling with simultaneous forming of tubing continuously, the stopping and the restarting of the downward silvance, the machine can also be used to make the internal sleeveing of tubes even if filled with water or to make the internal sleeving of a superturnal As these various circum can be or any form and as they are not part of the inwention insofar as the application of the
units, which can be obtained from trade
sources, is concerned, it has not been
deemed necessary to illustrate in detail
each control, whose structure may take any
form. The control of resin flow limits such
flows to a rate of increase of 10%. Thus the internal sleeving of a punctured or completely endised tube.

Finally, the controls for advancing the tool downwards by means of sleeves 11, 12 and cylinder 42, can be reversed to return the controls of the controls of the control of the cont flows to a rate of increase of 10%. Thus, even if the bore hole passes through an underground cavern which may be present in the strata, the increase in resis flow will and cyanger 44, can on reverses to return the assembly to a desired depth, as for example when restarting the tubing process with the object of commerting it to the previously formed portion. only lead to a flight increase in rests flow will only lead to a flight increase in sleeve and tubing thicknesses in the region of the cavern. Again it will be noted that although such caverns are usually filled with water, it is always possible to make the sleeve because the material thereof is selected to be able to polymerize in water. As the tribute WHAT WE CLAIM IS:—

1. A method of exploratory drilling comprising drilling a hole and moulding a tubing around the wall of the drilled hole simultaneously with drilling of the hole, the tube preventing caving in of the strata and ingress of water.

2. A method of exploratory drilling commission drilling be able to polymerise in water. As the tubing be able to polymerise in water. As the tubing is protected by the shows, the tubing can still be moulded normally.

If drilling must be interrupted, the flow of hardener is stopped by means of valves 37 and the resin circuits are drained of hardener. If drilling recommences, a start is made by machining the luner wall of the bottom part of the tubing a few yards above 2. A method of exploratory drilling comprising drilling a hole by passing a drilling tool downwardly through the earth, moulding a tubing around the wall of the
